Let's Start!

Issues When Typing Data

Learning Outcome:

Designs the data structure based on the database structures and its characteristics.

Validate database using the proper IT tools.

Can Do Statements:

- I can talk about common issues in data validation.
- I can describe field level validation.
- I can explain what form level validation is.

Ask your partner:

- What are the most common mistakes people make when typing on a computer? List them.
- What strategies do you apply to verify the final version of the information you typed?

Let's Explore!

Ops! That was my fault* when I registered the information.

*"My fault" is used to blame oneself for a mistake or error.

Instructions: Read the text below.

Registering data and information into databases won't be a flawless activity as errors are easy to commit. Two are the most common slips that we can commit when it comes to registering important pieces of information in databases or systems. Whenever we have got to transfer data from one main source, such as a customer, to a database, there is a high chance of us committing transcription errors. These will not occur unless we misread or mishear elements like numbers, foreign names or addresses introducing wrong pieces of information into the system. Another common type of error is the transposition error in which we unintentionally change similar pieces of information in numbers or words to other similar values without noticing it.

Different built-in tools are going to help users prevent other types of mistakes. This is the case of the field level validation, which avoids the errors caused by the human interaction with the system as it portrays a series of different pre-established fields for the user to completely fill in a given order and way. If the data is not correct, it won't be registered in the database; in fact, the user will be alerted about the error. For example, email addresses that lack the "@" symbol are going to be rejected.

Finally, the form level validation is going to ensure that the user fills all the *de rigueur* data and that all special requirements are met before the data is submitted. This validation has got to be performed once the form is completely filled in order to proceed with a whole validation of the input that was introduced. Furthermore, this type of validation will not let the user register the form if there's missing information on a required field marked with a "*" symbol.

Let's Practice!

Some Common Mistakes in Data Validation

Instructions: Select all the correct answers.

1. Which of these are common errors in data validation?
 - a. Misread elements like numbers.
 - b. Transfer data from a main source without transcription errors.
 - c. Mishear elements such as foreign names or addresses.
 - d. Unintentionally change similar pieces of information in numbers or words.
 - e. Notice when we change unintentionally similar values.

Let's Practice!

Some Benefits of the Validation Process

Instructions: Select the correct option to correctly complete each sentence.

Registering data and information into databases (won't be / want to be / will be) a flawless activity. Errors are easy to commit and the built-in tools (won't prevent / prevent / preventing) all types of mistakes; however, these tools (will / won't be / will be) help users to make all the processes easier.

Extension Activity

Let's study more about level validation for data.

Instructions: Complete the following steps. Fill in the Self-Assessment.

- Look for more information about field level validation and form level validation.
- Make a comparative chart in which you describe all their features and the procedures step by step.
- Share your chart with the rest of the class.

Self-Assessment

Yes No

- I look for information about level validation.
- I describe level validation procedures step by step.
- I talk about different kinds of level validation and its features in a software implementation.

☐	☐
☐	☐

Target Words

- notice** (verb): to realize or see with attention
e.g. You won't notice wrong pieces of information if you misread or mishear elements.
- lack** (noun): the absence of an element
e.g. For example, email addresses that lack the "@" symbol are going to be rejected.
- de rigueur** (adjective): necessary, vital to something
e.g. Finally, the form level validation is going to ensure that the user fills all the de rigueur data and that all special requirements are met before the data is submitted.
- commit** (verb): to make
e.g. Registering data and information into databases won't be a flawless activity as errors are easy to commit.
- slip** (noun): a slight mistake
e.g. Two are the most common slips that we can commit when it comes to registering important pieces of information in databases or systems.
- unintentionally** (adverb): not intended to happen
e.g. Another common type of error is the transposition error in which we unintentionally change similar pieces of information in numbers or words to other similar values without noticing it.

Learning Points

The Future With Will- Negative Form

You use **"will"** to talk about future actions.

You use **won't** to talk about improbable situations in the future. You can also use it to give promises or to talk about decisions taken spontaneously. As the form, **will** does not imply that something will happen for sure, certain expressions like *probably*, *maybe* or *I think* can be used.

The negative form of this expression is **will not** or its abbreviation **won't**

Example:

*Maybe, registering data and information into databases **won't** be a flawless activity as errors are easy to commit.*

Examples

- *Registering data and information into databases won't be a flawless activity as errors are easy to commit.*
- *Furthermore, this type of validation will not let the user register the form if there's missing information on a required field marked with a "*" symbol.*

Common Issues in Data Validation

The fact that data is registered manually makes the data validation process not exempt from errors and mistakes.

Human error is likely to happen throughout the data registration of any database or application. That is why different types of data validation are applied in order to avoid as much as possible the most common issues in this process. However, chances of users, and even professionals, entering 100% correct and accurate data to software systems and data bases are not as high as expected. Two are the most common errors that any of us can commit when it comes to register data.

1. TRANSCRIPTION ERRORS

The fact of transferring data or pieces of information from one source to the database or system can be a tricky chore. All sorts of errors can be made whenever we manually register information; more specifically, misreading or mishearing information such as long numbers or foreign names are easy to confuse.

For example,

"Simpson" may be confused by "Simson".

"Simon" may be confused by "Simone"

2. TRANSPOSITION ERRORS

Transposition errors occur whenever pieces of information such as numbers or words are unintentionally changed when we interchange two consecutive or similar numbers or words. There are cases in which similar values or letter can be confused and registered in the databases.

For example,

"1956" can be unintentionally changed to "1965".

"Clark" can be unintentionally changed to "Clerk" or "Clakr".
